High Common-Mode Voltage Programmable Gain Difference Amplifier

AD628

FEATURES

High common-mode input voltage range
- **±120 V at V_S = ±15 V**

Gain range 0.1 to 100

Operating temperature range: −40°C to ±85°C

Supply voltage range
- **Dual supply: ±2.25 V to ±18 V**
- **Single supply: 4.5 V to 36 V**

Excellent ac and dc performance

Offset temperature stability RTI: 10 µV/°C max

Offset: ±1.5 V mV max

CMRR RTI: 75 dB min, dc to 500 Hz, G = +1

APPLICATIONS

High voltage current shunt sensing

Programmable logic controllers

Analog input front end signal conditioning
- **+5 V, +10 V, ±5 V, ±10 V and 4 to 20 mA**

Isolation

Sensor signal conditioning

Power supply monitoring

Electrohydraulic control

Motor control

GENERAL DESCRIPTION

The AD628 is a precision difference amplifier that combines excellent dc performance with high common-mode rejection over a wide range of frequencies. When used to scale high voltages, it allows simple conversion of standard control voltages or currents for use with single-supply ADCs. A wideband feedback loop minimizes distortion effects due to capacitor charging of Σ-Δ ADCs.

A reference pin (V_{REF}) provides a dc offset for converting bipolar to single-sided signals. The AD628 converts +5 V, +10 V, ±5 V, ±10 V, and 4 to 20 mA input signals to a single-ended output within the input range of single-supply ADCs.

The AD628 has an input common-mode and differential mode operating range of ±120 V. The high common-mode input impedance makes the device well suited for high voltage measurements across a shunt resistor. The buffer amplifier's inverting input is available for making a remote Kelvin connection.

A precision 10 kΩ resistor connected to an external pin is provided for either a low-pass filter or to attenuate large differential input signals. A single capacitor implements a low-pass filter. The AD628 operates from single and dual supplies and is available in an 8-lead SOIC or MSOP package. It operates over the standard industrial temperature range of −40°C to +85°C.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The AD628 is a high common-mode voltage difference amplifier, combined with a user configurable output amplifier (see Figure 28 and Figure 29). Differential mode voltages in excess of 120 V are accurately scaled by a precision 11:1 voltage divider at the input. A reference voltage input is available to the user at Pin 3 (V_{REF}). The output common-mode voltage of the difference amplifier is the same as the voltage applied to the reference pin. If the uncommitted amplifier is configured for gain, connecting Pin 3 to one end of the external gain resistor establishes the output common-mode voltage at Pin 5 (OUT).

The output of the difference amplifier is internally connected to a 10 kΩ resistor trimmed to better than ±0.1% absolute accuracy. The resistor is connected to the noninverting input of the output amplifier and is accessible to the user at Pin 4 (C_{FILT}). A capacitor may be connected to implement a low-pass filter, a resistor may be connected to further reduce the output voltage, or a clamp circuit may be connected to limit the output swing.

The uncommitted amplifier is a high open-loop gain, low offset, low drift op amp, with its noninverting input connected to the internal 10 kΩ resistor. Both inputs are accessible to the user.

Careful layout design has resulted in exceptional common-mode rejection at higher frequencies. The inputs are connected to Pin 1 (+IN) and Pin 8 (−IN), which are adjacent to the power Pin 2 ($-V_S$) and Pin 7 ($+V_S$). Because the power pins are at ac ground, input impedance balance and, therefore, common-mode rejection, are preserved at higher frequencies.

APPLICATIONS

GAIN ADJUSTMENT

The AD628 system gain is provided by an architecture consisting of two amplifiers. The gain of the input stage is fixed at 0.1; the output buffer is user adjustable as $G_{A2} = 1 + R_{EXT1}/R_{EXT2}$. The system gain is then

$$G_{TOTAL} = 0.1 \times \left(1 + \frac{R_{EXT1}}{R_{EXT2}}\right) \quad (1)$$

At a 2 nA maximum, the input bias current of the buffer amplifier is very low and any offset voltage induced at the buffer amplifier by its bias current may be neglected (2 nA × 10 kΩ = 20 μV). However, to absolutely minimize bias current effects, R_{EXT1} and R_{EXT2} may be selected so that their parallel combination is 10 kΩ. If practical resistor values force the parallel combination of R_{EXT1} and R_{EXT2} below 10 kΩ, a series resistor (R_{EXT3}) may be added to make up for the difference. Table 5 lists several values of gain and corresponding resistor values.

Table 5. Nearest Standard 1% Resistor Values for Various Gains (See Figure 29)

Total Gain (V/V)	A2 Gain (V/V)	R_{EXT1} (Ω)	R_{EXT2} (Ω)	R_{EXT3} (Ω)
0.1	1	10 k	∞	0
0.2	2	20 k	20 k	0
0.25	2.5	25.9 k	18.7 k	0
0.5	5	49.9 k	12.4 k	0
1	10	100 k	11 k	0
2	20	200 k	10.5 k	0
5	50	499 k	10.2 k	0
10	100	1 M	10.2 k	0

To set the system gain to less than 0.1, an attenuator may be created by placing a resistor, R_{EXT4}, from Pin 4 (C_{FILT}) to the reference voltage. A divider would be formed by the 10 kΩ resistor which is in series with the positive input of A2 and R_{EXT4}. A2 would be configured for unity gain.

Using a divider and setting A2 to unity gain yields

$$G_{W/DIVIDER} = 0.1 \times \left(\frac{R_{EXT4}}{10\ \text{k}\Omega + R_{EXT4}}\right) \times 1$$

INPUT VOLTAGE RANGE

The common-mode input voltage range is determined by V_{REF} and the supply voltage. The relation is expressed by

$$\begin{aligned} V_{CM_{UPPER}} &\leq 11(V_{S+} - 1.2\ \text{V}) - 10\ V_{REF} \\ V_{CM_{LOWER}} &\geq 11(V_{S-} + 1.2\ \text{V}) - 10\ V_{REF} \end{aligned} \quad (2)$$

where V_{S+} is the positive supply, V_{S-} is the negative supply and 1.2 V is the headroom needed for suitable performance. Equation 2 provides a general formula for calculating the common-mode input voltage range. However, the AD628 should be kept within the maximum limits listed in the Specifications table (Table 1) to maintain optimal performance. This is illustrated in Figure 30 where the maximum common-mode input voltage is limited to ±120 V. Figure 31 shows the common-mode input voltage bounds for single-supply voltages.

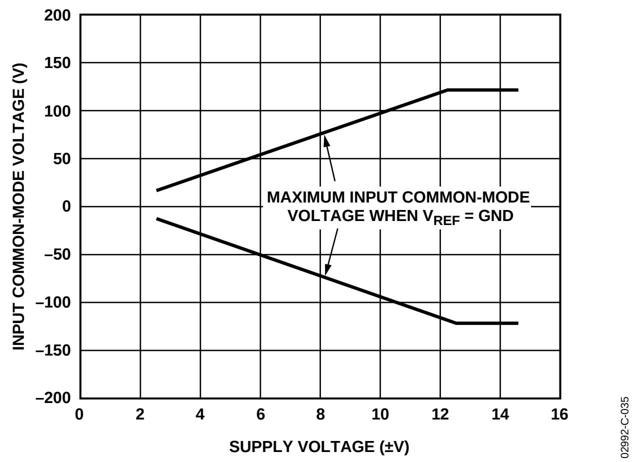

Figure 30. Input Common-Mode Voltage vs. Supply Voltage for Dual Supplies

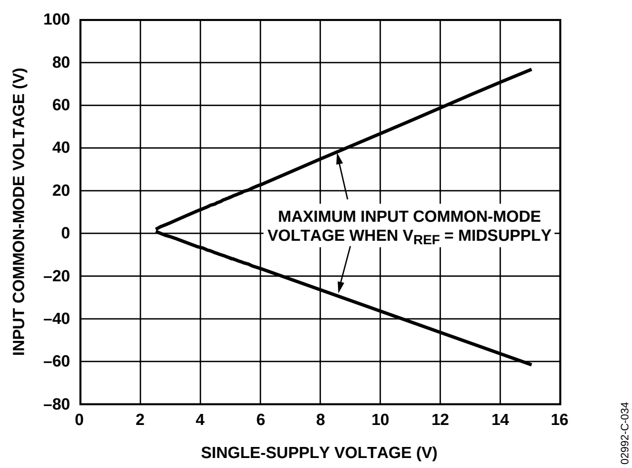

Figure 31. Input Common-Mode Voltage vs. Supply Voltage for Single Supplies

The differential input voltage range is constrained to the linear operation of the internal amplifiers A1 and A2. The voltage applied to the inputs of A1 and A2 should be between V_{S-} + 1.2 V and V_{S+} − 1.2 V. Similarly, the outputs of A1 and A2 should be kept between V_{S-} + 0.9 V and V_{S+} − 0.9 V.

VOLTAGE LEVEL CONVERSION

Industrial signal conditioning and control applications typically require connections between remote sensors or amplifiers and centrally located control modules. Signal conditioners provide output voltages up to ±10 V full scale; however, ADCs or microprocessors operating on single 3.3 V to 5 V logic supplies are becoming the norm. Thus, the controller voltages require further reduction in amplitude and reference.

Furthermore, voltage potentials between locations are seldom compatible, and power line peaks and surges can generate destructive energy between utility grids. The AD628 is an ideal solution to both problems. It attenuates otherwise destructive signal voltage peaks and surges by a factor of 10 and shifts the differential input signal to the desired output voltage.

Conversion from voltage-driven or current-loop systems is easily accommodated using the circuit in Figure 32. This shows a circuit for converting inputs of various polarities and amplitudes to the input of a single-supply ADC.

Note that the common-mode output voltage can be adjusted by connecting Pin 3 (V_{REF}) and the lower end of the 10 kΩ resistor to the desired voltage. The output common-mode voltage will be the same as the reference voltage.

The design of such an application may be done in a few simple steps, which include the following:

- Determine the required gain. For example, if the input voltage must be transformed from ±10 V to 0 V to +5 V, the gain is +5/+20 or +0.25.
- Determine if the circuit common-mode voltage must be changed. An AD7715-5 ADC is illustrated for this example. When operating from a 5 V supply, the common-mode voltage of the AD7715 is half the supply or 2.5 V. If the AD628 reference pin and the lower terminal of the 10 kΩ resistor are connected to a 2.5 V voltage source, the output common-mode voltage will be 2.5 V.

Table 6 shows resistor and reference values for commonly used single-supply converter voltages. R_{EXT3} is included as an option. It is used to balance the source impedance into A2, which is described in more detail in the Gain Adjustment section.

CURRENT LOOP RECEIVER

Analog data transmitted on a 4 to 20 mA current loop may be detected with the receiver shown in Figure 33. The AD628 is an ideal choice for such a function, because the current loop must be driven with a compliance voltage sufficient to stabilize the loop, and the resultant common-mode voltage often exceeds commonly used supply voltages. Note that with large shunt values a resistance of equal value must be inserted in series with the inverting input to compensate for an error at the noninverting input.

MONITORING BATTERY VOLTAGES

Figure 34 illustrates how the AD628 may be used to monitor a battery charger. Voltages approximately eight times the power supply voltage may be applied to the input with no damage. The resistor divider action is well suited for the measurement of many power supply applications, such as those found in battery chargers or similar equipment.

FILTER CAPACITOR VALUES

A capacitor may be connected to Pin 4 (C_{FILT}) to implement a low-pass filter. The capacitor value is

$$C = 15.9/f_t\,(\mu F)$$

where f_t is the desired 3 dB filter frequency.

Table 7 shows several frequencies and their closest standard capacitor values.

KELVIN CONNECTION

In certain applications, it may be desirable to connect the inverting input of an amplifier to a remote reference point. This eliminates errors resulting in circuit losses in interconnecting wiring. The AD628 is particularly suited for this type of connection. In Figure 35, a 10 kΩ resistor is added in the feedback to match the source impedance of A2, which is described in more detail in the Gain Adjustment section.
