

COP413C/COP413CH/COP313C/COP313CH Single-Chip CMOS Microcontrollers

General Description

The COP413C, COP413CH, COP313C, and COP313CH fully static, single-chip CMOS microcontrollers are members of the COPSTM family, fabricated using double-poly, silicongate CMOS technology. These controller-oriented processors are complete microcomputers containing all system timing, internal logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, with an instruction set, internal architecture, and I/O scheme designed to facilitate keyboard input, display output, and BCD data manipulation. The COP413CH is identical to the COP413C except for operating voltage and frequency. They are an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide a customized controller-oriented processor at a low end-product cost.

The COP313C/COP313CH is the extended temperature range version of the COP413C/COP413CH.

For emulation use the ROMless COP404C.

Features

- U Lowest power dissipation (40 μ W typical)
- **Low cost**
- Power-saving HALT Mode
- \blacksquare Powerful instruction set
- \blacksquare 512 x 8 ROM, 32 x 4 RAM
- \blacksquare 15 I/O lines
- \blacksquare Two-level subroutine stack
- \blacksquare DC to 4 μ s instruction time
- \blacksquare Single supply operation (3V to 5.5V)
- General purpose and TRI-STATE[®] outputs
- Internal binary counter register with MICROWIRETM compatible serial I/O
- Software/hardware compatible with other members of the COP400 family
- Extended temperature (-40° C to $+85^{\circ}$ C) devices available

Development Support

The MOLE (Microcontroller On Line Emulator) is a low cost development system and real time emulator for COPS' products. They also include TMP, 8050 and the new 16 bit HPC microcontroller family. The MOLE provides effective support for the development of both software and hardware in the user's application.

The purpose of the MOLE is to provide a tool to write and assemble code, emulate code for the target microcontroller and assist in debugging of the system.

The MOLE can be connected to various hosts, IBM PC, STARPLEXTM, Kaypro, Apple and Intel systems, via RS-232 port. This link facilitates the up loading/down loading of code, supports host assembly and mass storage.

The MOLE consists of three parts; brain, personality and optional host software.

The brain board is the computing engine of the system. It is a self-contained computer with its own firmware which provides for all system operation, emulation control, communication, from programming and diagnostic operation. It has three serial ports which can be connected to a terminal, host system, printer, modem or to other MOLE's in a multi-MOLE environment.

The personality board contains the necessary hardware and firmware needed to emulate the target microcontroller. The emulation cable which replaces the target controller attaches to this board. The software contains a cross assembler and a communications program for up loading and down loading code from the MOLE.

Functional Description

To ease reading of this description, only COP413C is referenced; however, all such references apply equally to COP413CH, COP313C, and COP313CH.

A block diagram of the COP413C is given in Figure 1. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic ''1''; when a bit is reset, it is a logic ''0''.

PROGRAM MEMORY

Program memory consists of a 512-byte ROM. As can be seen by an examination of the COP413C instruction set, these words may be program instructions, program data, or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID, and LQID instructions, ROM must often be thought of as being organized into 8 pages of 64 words (bytes) each.

ROM ADDRESSING

ROM addressing is accomplished by a 9-bit PC register. Its binary value selects one of the 512 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 9-bit binary count value. Two levels of subroutine nesting are implemented by two 9-bit subroutine save registers, SA and SB.

ROM instruction words are fetched, decoded, and executed by the instruction decode, control and skip logic circuitry.

DATA MEMORY

Data Memory consists of a 128-bit RAM, organized as four data registers of 8 \times 4-bit digits. RAM addressing is implemented by a 6-bit B register whose upper two bits (Br) selects one of four data registers and lower three bits of the 4 bit Bd select one of eight 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) are usually loaded into or from, or exchanged with, the A register (accumulator), they may also be loaded into the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the XAD 3, 15 instruction.

The most significant bit of Bd is not used to select a RAM digit. Hence, each physical digit of RAM may be selected by two different values of Bd as shown in Figure 4. The skip condition for XIS and XDS instructions will be true if Bd changes between 0 to 15, but not between 7 and 8 (see Table III).

INTERNAL LOGIC

The internal logic of the COP413C is designed to ensure fully static operation of the device.

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Bd portion of the B register, to load four bits of the 8-bit Q latch data and to perform data exchanges with the SIO register.

The 4-bit adder performs the arithmetic and logic functions of the COP413C, storing its results in A. It also outputs the carry information to a 1-bit carry register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description below.)

The G register contents are outputs to four general purpose bidirectional I/O ports.

The Q register is an internal, latched, 8-bit register, used to hold data loaded from RAM and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The eight L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and RAM.

FIGURE 4. RAM Digit Address to Physical RAM Digit Mapping

Functional Description (Continued)

The SIO register functions as a 4-bit serial-in/serial-out shift register or as a binary counter, depending upon the contents of the EN register. (See EN register description below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. With SIO functioning as a serial-in/serial-out shift register and SK as a sync clock, the COP413C is MICROWIRE compatible. The XAS instruction copies C into the SKL latch. In the counter mode, SK is the output of SKL; in the shift register mode, SK is a sync clock, inhibited when SKL is a logic ''0''. The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN3 –EN0).

- 1. The least significant bit of the enable register, EN0, selects the SIO register as either a 4-bit shift register or as a 4-bit binary counter. With EN0 set, SIO is an asynchronous binary counter, decrementing its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN3. With EN0 reset, SIO is a serial shift register, shifting left each instruction cycle time. The data present at SI is shifted into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each instruction cycle time. (See 4, below.) The SK output becomes a logic-controlled clock.
- 2. EN 1 is not used, it has no effect on the COP413C.
- 3. With EN2 set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN2 disables the L drivers, placing the L I/O ports in a high impedance input state.
- 4. EN3, in conjunction with EN0, affects the SO output. With EN0 set (binary counter option selected), SO will output the value loaded into EN3. With EN0 reset (serial shift

register option selected), setting EN3 enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN3 with the serial shift register option selected, disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0".

INITIALIZATION

The external RC network shown in Figure 5 must be connected to the RESET pin. The RESET pin is configured as a Schmitt trigger input. If not used, it should be connected to V_{CC}. Initialization will occur whenever a logic "0" is applied to the RESET input, providing it stays low for at least three instruction cycle times.

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. Data memory (RAM) is not cleared upon initialization. The first instruction at address 0 must be a CLRA (clear A register).

 $RC > 5 \times$ Power Supply Rise Time and $RC > 100 \times CKI$ Period

FIGURE 5. Power-Up Clear Circuit

TABLE I. Enable Register Modes-Bits EN0 and EN3

Functional Description (Continued)

HALT MODE

The COP413C is a fully static circuit; therefore, the user may stop the system oscillator at any time to halt the chip. The chip may be halted by the HALT instruction. Once in the HALT mode, the internal circuitry does not receive any clock signal, and is therefore frozen in the exact state it was in when halted. All information is retained until continuing. The HALT mode is the minimum power dissipation state.

The HALT mode may be entered into by program control (HALT instruction) which forces CKO to a logic ''1'' state. The circuit can be awakened only by the RESET function.

POWER DISSIPATION

The lowest power drain is when the clock is stopped. As the frequency increases so does current. Current is also lower at lower operating voltages. Therefore, to minimize power consumption, the user should run at the lowest speed and voltage that his application will allow. The user should take care that all pins swing to full supply levels to ensure that outputs are not loaded down and that inputs are not at some intermediate level which may draw current. Any input with a slow rise or fall time will draw additional current. A crystal- or resonator-generated clock will draw more than a square-wave input. An RC oscillator will draw even more current since the input is a slow rising signal.

If using an external squarewave oscillator, the following equation can be used to calculate the COP413C current drain.

- $Ic = Iq + (V \times 20 \times Fi) + (V \times 1280 \times FI/DV)$
	- where $Ic =$ chip current drain in microamps
		- $Iq = quiescent$ leakage current (from curve)
		- $FI = CKI$ frequency in megahertz
		- $V =$ chip V_{CC} in volts
		- $Dv =$ divide by option selected

For example, at 5V V_{CC} and 400 kHz (divide by 8), $Ic = 30 + (5 \times 20 \times 0.4) + (5 \times 1280 \times 0.4/8)$ $1c = 30 + 40 + 320 = 390 \mu A$

OSCILLATOR OPTIONS

There are two options available that define the use of CKI and CKO.

- a. Cyrstal-Controlled Oscillator. CKI and CKO are connected to an external crystal. The instruction cycle time equals the crystal frequency divided by 8.
- b. RC-Controlled Oscillator. CKI is configured as a single pin RC-controlled Schmitt trigger oscillator. The instruction cycle equals the oscillation frequency divided by 4. CKO is NC.

The RC oscillator is not recommended in systems that require accurate timing or low current. The RC oscillator draws more current than an external oscillator (typically an additional 100 μ A at 5V). However, when the part halts, it stops with CKI high and the halt current is at the minimum.

FIGURE 6. COP413C Oscillator

Functional Description (Continued)

I/O CONFIGURATIONS

COP413C outputs have the following configurations, illustrated in Figure ⁷:

- a. Standard SO, SK Output. A CMOS push-pull buffer with an N-channel device to ground in conjunction with a P-channel device to V_{CC} , compatible with CMOS and LSTTL.
- b. Low Current G Output. This is the same configuration as (a) above except that the sourcing current is much less.
- c. Standard TRI-STATE L Output. L output is a CMOS output buffer similar to (a) which may be disabled by pro-

The SI and RESET inputs are Hi-Z inputs (Figure 7d).

When using the G I/O port as an input, set the output register to a logic ''1'' level. The P-channel device will act as a pull-up load. When using the L I/O port as an input, disable the L drivers with the LEI instruction. The drivers are then in TRI-STATE mode and can be driven externally.

All output drivers use one or more of three common devices numbered 1 to 3. Minimum and maximum current $(I_{OUT}$ and V_{OUT}) curves are given in Figure 8 for each of these devices to allow the designer to effectively use these I/O configurations.

COP413C Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table III provides the mnemonic, operand, machine code, data flow, skip conditions and description associated with each instruction in the COP413C instruction set.

TABLE II. COP413C Instruction Set Table Symbols

Range of values

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP413C programs.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register.) If SIO is selected as a shift register, an XAS instruction must be performed once every four instruction cycle times to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower eight bits of the ROM address register PC with the contents of ROM addressed by the 9-bit word, PC_8 , A, M. PC_8 is not affected by this instruction.

Note: JID uses two instruction cycles if executed, one if skipped.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 9-bit word PC₈, A, M. LQID can be used for table look-up or code conversion such as BCD to 7-segment. The LQID instruction ''pushes'' the stack (PC + $1 \rightarrow$ SA \rightarrow SB) and replaces the least significant eight bits of the PC as follows: A \rightarrow PC_{7:4}, $RAM(B)$ \rightarrow PC_{3:0}, leaving PC₈ unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SB \rightarrow SA \rightarrow PC), restoring the saved value of the PC to continue sequential program execution. Since LQID pushes $SA \rightarrow$ SB, the previous contents of SB are lost.

Note: LQID uses two instruction cycles if executed, one if skipped.

INSTRUCTION SET NOTES

- a. The first word of a COP413C program (ROM address 0) must be a CLRA (Clear A) instruction.
- b. Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths take the same number of cycle times whether instructions are skipped or executed (except JID and LQID).
- c. The ROM is organized into eight pages of 64 words each. The program counter is a 9-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID, or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: A JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word in page 3 or 7 will access data in the next group of four pages.

COPS Programming Manual

For detailed information on writing. COPS programs, the COPS Programming Manual 424410284-001 provides an indepth discussion of the COPS architecture, instruction set and general techniques of COPS programming. This manual is written with the programmer in mind.

OPTION LIST-OSCILLATOR SELECTION

The oscillator option selected must be sent in with the EPROM of ROM Code for masking into the COP413C. Select the appropriate option, make a photocopy of the table and send it with the EPROM.

COP413C/COP313C

Option 1: Oscillator selection

- $= 0$ Ceramic Resonator input frequency divided by 8. CKO is oscillator output.
- $=$ 1 Single pin RC controlled oscillator divided by 4. CKO is no connection.

Note: The following option information is to be sent to National along with the EPROM.

Option 1: Value $=$ $\frac{1}{2}$ is Oscillator Selected.

National does not assume any responsibility for use of any circuitry described, no circuit patent licenses are implied and National reserves the right at any time without notice to change said circuitry and specifica
