

Single Supply, Low Power, Triple Video Amplifier

AD8013

FEATURES

- Three Video Amplifiers in One Package
- Drives Large Capacitive Load
- Excellent Video Specifications ($R_L = 150 \Omega$)
 - Gain Flatness 0.1 dB to 60 MHz
 - 0.02% Differential Gain Error
 - 0.06° Differential Phase Error
- Low Power
 - Operates on Single +5 V to +13 V Power Supplies
 - 4 mA/Amplifier Max Power Supply Current
- High Speed
 - 140 MHz Unity Gain Bandwidth (3 dB)
 - Fast Settling Time of 18 ns (0.1%)
 - 1000 V/ μ s Slew Rate
- High Speed Disable Function per Channel
 - Turn-Off Time 30 ns
- Easy to Use
 - 95 mA Short Circuit Current
 - Output Swing to Within 1 V of Rails

APPLICATIONS

- LCD Displays
- Video Line Driver
- Broadcast and Professional Video
- Computer Video Plug-In Boards
- Consumer Video
- RGB Amplifier in Component Systems

PRODUCT DESCRIPTION

The AD8013 is a low power, single supply, triple video amplifier. Each of the three amplifiers has 30 mA of output current, and is optimized for driving one back terminated video load (150Ω) each. Each amplifier is a current feedback amplifier and features gain flatness of 0.1 dB to 60 MHz while offering

Fine-Scale Gain Flatness vs. Frequency, $G = +2$, $R_L = 150 \Omega$

REV. A

PIN CONFIGURATION

14-Pin DIP & SOIC Package

differential gain and phase error of 0.02% and 0.06°. This makes the AD8013 ideal for broadcast and professional video electronics.

The AD8013 offers low power of 4 mA per amplifier max and runs on a single +5 V to +13 V power supply. The outputs of each amplifier swing to within one volt of either supply rail to easily accommodate video signals. The AD8013 is unique among current feedback op amps by virtue of its large capacitive load drive. Each op amp is capable of driving large capacitive loads while still achieving rapid settling time. For instance it can settle in 18 ns driving a resistive load, and achieves 40 ns (0.1%) settling while driving 200 pF.

The outstanding bandwidth of 140 MHz along with 1000 V/ μ s of slew rate make the AD8013 useful in many general purpose high speed applications where a single +5 V or dual power supplies up to ± 6.5 V are required. Furthermore the AD8013's high speed disable function can be used to power down the amplifier or to put the output in a high impedance state. This can then be used in video multiplexing applications. The AD8013 is available in the industrial temperature range of -40°C to $+85^\circ\text{C}$.

Channel Switching Characteristics for a 3:1 Mux

NOTES

¹The test circuit for differential gain and phase measurements on a +5 V supply is ac coupled. Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS¹

- Supply Voltage 13.2 V Total
- Internal Power Dissipation²
 - Plastic (N) 1.6 Watts (Observe Derating Curves)
 - Small Outline (R) 1.0 Watts (Observe Derating Curves)
- Input Voltage (Common Mode) . . Lower of ±V_S or ±12.25 V
- Differential Input Voltage Output ±6 V (Clamped)
- Output Voltage Limit
 - Maximum Lower of (+12 V from -V_S) or (+V_S)
 - Minimum Higher of (-12.5 V from +V_S) or (-V_S)
- Output Short Circuit Duration
 - Observe Power Derating Curves
- Storage Temperature Range
 - N and R Package -65°C to +125°C
- Operating Temperature Range
 - AD8013A -40°C to +85°C
- Lead Temperature Range (Soldering 10 sec) +300°C

NOTES

¹Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

²Specification is for device in free air:

14-Pin Plastic DIP Package: θ_{JA} = 75°C/Watt

14-Pin SOIC Package: θ_{JA} = 120°C/Watt

| AD8013ACHIPS | -40°C to +85°C | Die Form | |

Maximum Power Dissipation

The maximum power that can be safely dissipated by the AD8013 is limited by the associated rise in junction temperature. The maximum safe junction temperature for the plastic encapsulated parts is determined by the glass transition temperature of the plastic, about 150°C. Exceeding this limit temporarily may cause a shift in parametric performance due to a change in the stresses exerted on the die by the package. Exceeding a junction temperature of 175°C for an extended period can result in device failure.

While the AD8013 is internally short circuit protected, this may not be enough to guarantee that the maximum junction temperature is not exceeded under all conditions. To ensure proper operation, it is important to observe the derating curves.

It must also be noted that in (noninverting) gain configurations (with low values of gain resistor), a high level of input overdrive can result in a large input error current, which may result in a significant power dissipation in the input stage. This power must be included when computing the junction temperature rise due to total internal power.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD8013 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

General

The AD8013 is a wide bandwidth, triple video amplifier that offers a high level of performance on less than 4.0 mA per amplifier of quiescent supply current. The AD8013 uses a proprietary enhancement of a conventional current feedback architecture, and achieves bandwidth in excess of 200 MHz with low differential gain and phase errors, making it an extremely efficient video amplifier.

The AD8013's wide phase margin coupled with a high output short circuit current make it an excellent choice when driving any capacitive load. High open-loop gain and low inverting input bias current enable it to be used with large values of feedback resistor with very low closed-loop gain errors.

It is designed to offer outstanding functionality and performance at closed-loop inverting or noninverting gains of one or greater.

Choice of Feedback & Gain Resistors

Because it is a current feedback amplifier, the closed-loop bandwidth of the AD8013 may be customized using different values of the feedback resistor. Table I shows typical bandwidths at different supply voltages for some useful closed-loop gains when driving a load of 150Ω .

The choice of feedback resistor is not critical unless it is important to maintain the widest, flattest frequency response. The resistors recommended in the table are those (chip resistors) that will result in the widest 0.1 dB bandwidth without peaking. In applications requiring the best control of bandwidth, 1% resistors are adequate. Package parasitics vary between the 14-pin plastic DIP and the 14-pin plastic SOIC, and may result in a slight difference in the value of the feedback resistor used to achieve the optimum dynamic performance. Resistor values and widest bandwidth figures are shown in parenthesis for the SOIC where they differ from those of the DIP. Wider bandwidths than those in the table can be attained by reducing the magnitude of the feedback resistor (at the expense of increased peaking), while peaking can be reduced by increasing the magnitude of the feedback resistor.

Increasing the feedback resistor is especially useful when driving large capacitive loads as it will increase the phase margin of the closed-loop circuit. (Refer to the section on driving capacitive loads for more information.)

To estimate the -3 dB bandwidth for closed-loop gains of 2 or greater, for feedback resistors not listed in the following table, the following single pole model for the AD8013 may be used:

$$ACL \approx \frac{G}{1 + SC_T (R_F + G_n rin)}$$

where: C_T = transcapacitance $\cong 1$ pF

R_F = feedback resistor

G = ideal closed loop gain

$$G_n = \left(1 + \frac{R_F}{R_G} \right) = \text{noise gain}$$

rin = inverting input resistance $\cong 150 \Omega$

ACL = closed loop gain

The -3 dB bandwidth is determined from this model as:

$$f_3 \approx \frac{1}{2 \pi C_T (R_F + G_n rin)}$$

This model will predict -3 dB bandwidth to within about 10% to 15% of the correct value when the load is 150Ω and $V_S = \pm 5$ V. For lower supply voltages there will be a slight decrease in bandwidth. The model is not accurate enough to predict either the phase behavior or the frequency response peaking of the AD8013.

It should be noted that the bandwidth is affected by attenuation due to the finite input resistance. Also, the open-loop output resistance of about 12Ω reduces the bandwidth somewhat when driving load resistors less than about 250Ω . (Bandwidths will be about 10% greater for load resistances above a few hundred ohms.)

Table I. -3 dB Bandwidth vs. Closed-Loop Gain and Feedback Resistor, $R_L = 150 \Omega$ (SOIC)

| V_S - Volts | Gain | R_F - Ohms | BW - MHz |
|---------------|------|--------------|-----------|
| ±5 | +1 | 2000 | 230 |
| | +2 | 845 (931) | 150 (135) |
| | +10 | 301 | 80 |
| | -1 | 698 (825) | 140 (130) |
| | -10 | 499 | 85 |
| +5 | +1 | 2000 | 180 |
| | +2 | 887 (931) | 120 (130) |
| | +10 | 301 | 75 |
| | -1 | 698 (825) | 130 (120) |
| | -10 | 499 | 80 |

Driving Capacitive Loads

When used in combination with the appropriate feedback resistor, the AD8013 will drive any load capacitance without oscillation. The general rule for current feedback amplifiers is that the higher the load capacitance, the higher the feedback resistor required for stable operation. Due to the high open-loop transresistance and low inverting input current of the AD8013, the use of a large feedback resistor does not result in large closed-loop gain errors. Additionally, its high output short circuit current makes possible rapid voltage slewing on large load capacitors.

For the best combination of wide bandwidth and clean pulse response, a small output series resistor is also recommended. Table II contains values of feedback and series resistors which result in the best pulse responses. Figure 29 shows the AD8013 driving a 300 pF capacitor through a large voltage step with virtually no overshoot. (In this case, the large and small signal pulse responses are quite similar in appearance.)

AD8013

Overload Recovery

The three important overload conditions are: input common-mode voltage overdrive, output voltage overdrive, and input current overdrive. When configured for a low closed-loop gain, the amplifier will quickly recover from an input common-mode voltage overdrive; typically in under 25 ns. When configured for a higher gain, and overloaded at the output, the recovery time will also be short. For example, in a gain of +10, with 15% overdrive, the recovery time of the AD8013 is about 20 ns (see Figure 30). For higher overdrive, the response is somewhat slower. For 6 dB overdrive, (in a gain of +10), the recovery time is about 65 ns.

Figure 30. 15% Overload Recovery, $G = +10$ ($R_F = 300 \Omega$, $R_L = 1 k\Omega$, $V_S = \pm 5 V$)

As noted in the warning under “Maximum Power Dissipation,” a high level of input overdrive in a high noninverting gain circuit can result in a large current flow in the input stage. Though this current is internally limited to about 30 mA, its effect on the total power dissipation may be significant.

High Performance Video Line Driver

At a gain of +2, the AD8013 makes an excellent driver for a back terminated 75 Ω video line (Figures 31, 32, and 33). Low differential gain and phase errors and wide 0.1 dB bandwidth can be realized. The low gain and group delay matching errors ensure excellent performance in RGB systems. Figures 34 and 35 show the worst case matching.

Figure 34. Closed-Loop Gain Matching vs. Frequency

Figure 35. Group Delay and Group Delay Matching vs. Frequency, $G = +2$, $R_L = 150 \Omega$

Disable Mode Operation

Pulling the voltage on any one of the Disable pins about 1.6 V up from the negative supply will put the corresponding amplifier into a disabled, powered down, state. In this condition, the amplifier’s quiescent current drops to about 0.3 mA, its output becomes a high impedance, and there is a high level of isolation from input to output. In the case of the gain of two line driver for example, the impedance at the output node will be about the same as for a 1.6 kΩ resistor (the feedback plus gain resistors) in parallel with a 12 pF capacitor and the input to output isolation will be about 66 dB at 5 MHz.

Leaving the Disable pin disconnected (floating) will leave the corresponding amplifier operational, in the enabled state. The input impedance of the disable pin is about 40 kΩ in parallel with a few picofarads. When driven to 0 V, with the negative supply at -5 V, about 100 μA flows into the disable pin.

When the disable pins are driven by complementary output CMOS logic, on a single 5 V supply, the disable and enable times are about 50 ns. When operated on dual supplies, level shifting will be required from standard logic outputs to the Disable pins. Figure 36 shows one possible method which results in a negligible increase in switching time.

Figure 36. Level Shifting to Drive Disable Pins on Dual Supplies

The AD8013’s input stages include protection from the large differential input voltages that may be applied when disabled. Internal clamps limit this voltage to about ±3 V. The high input to output isolation will be maintained for voltages below this limit.

3:1 Video Multiplexer

Wiring the amplifier outputs together will form a 3:1 mux with excellent switching behavior. Figure 37 shows a recommended configuration which results in -0.1 dB bandwidth of 35 MHz and OFF channel isolation of 60 dB at 10 MHz on ±5 V supplies. The time to switch between channels is about 50 ns. Switching time is virtually unaffected by signal level.

Figure 37. A Fast Switching 3:1 Video Mux (Supply Bypassing Not Shown)

Figure 38. Channel Switching Characteristic for the 3:1 Mux

AD8013

2:1 Video Multiplexer

Configuring two amplifiers as unity gain followers and using the third to set the gain results in a high performance 2:1 mux (Figures 39 and 40). This circuit takes advantage of the very low crosstalk between Channels 2 and 3 to achieve the OFF channel isolation shown in Figure 40. This circuit can achieve differential gain and phase of 0.03% and 0.07° respectively.

Figure 39. 2:1 Mux with High Isolation and Low Differential Gain and Phase Errors

Figure 40. 2:1 Mux ON Channel Gain and Mux OFF Channel Feedthrough vs. Frequency

Gain Switching

The AD8013 can be used to build a circuit for switching between any two arbitrary gains while maintaining a constant input impedance. The example of Figure 41 shows a circuit for switching between a noninverting gain of 1 and an inverting gain of 1. The total time for channel switching and output voltage settling is about 80 ns.
